

coffee_shop: Investigations into modern word processors.

Nathaniel Welch, Dr. Clark Turner

California State Polytechnic University

June 13, 2011

Abstract

My senior project was spent building a desktop application similar to WriteRoom and OmmWriter. These two applications are both word processors for the Macintosh OS X operating system. Both of these applications are designed to be a reset on word processing software, bringing their interfaces back to the days of Microsoft Word 3.0 and Word Perfect. They do this by spending more time on focusing on the design of the software interface, and focusing on keeping it minimalistic, instead of filling the product with new obscure features, which is a common complaint against the current iterations of Microsoft Word.

The final application, named coffee_shop, ended up not meeting my expectations. Having spent most of my education developing applications for the internet, instead of the desktop, I ran into pitfalls which, if this had been an internet application, wouldn't have been as problematic.

1 Introduction

Depending on the job, people use different tools. Some tools are incredibly specialised, such as post hole diggers and PVC pipe warmers. Others are much more generic, such as hammers and cameras. Notice though, that in the hardware world, the majority of tools serve one job. That job, such as hammering, can be applied to a wide variety of ways (hammering in a nail, breaking apart structures, putting stakes in the ground). In the software world, tools have historically been built to be much more generic. Microsoft Word, for example, not only let the user write documents, but also let them create spreadsheets, resumes and many other things. While this has let Microsoft make more money by selling their software to a wider variety of users, it has created software that is hard to use and hard to maintain. To fight this, companies and individuals are starting to create software that have less features, are easier to use and focus on solving one specific problem.

2 Problem description

The problem `coffee_shop` tries to tackle is whether or not developing a desktop application focused on writing, instead of formatting, is a good idea.

3 Survey of relevant work

Before starting the project, I surveyed a variety of word processing programs and interviewed individuals about their writing habits. The survey I distributed was simple and open-ended. I asked users what types of documents they wrote, what they disliked about their current word processor and what they liked and wanted in their word processor.

I discovered that there were two groups of users of word processors in my survey group. There were those who wrote in a corporate or academic environment and those that wrote for themselves. The users that wrote more for academia and corporate positions tended to want lots of formatting options. Users who wrote for themselves or wrote fiction usually wanted something that hid everything and let them just write.

Every single one of my responders despised Microsoft Word's auto-correct but thought spell check was the most essential feature any word processor could have.

I decided to name my user group Johnny, based on two different people that I interviewed and the responses from my survey. Johnny writes fiction in his free time and aspires to be a writer. He is currently

Figure 1: Microsoft Word 2010 with no text.

employed doing other things, so he uses his word processor as he commutes and during his time off. Most of what Johnny writes tends to be one or two pages, but he has been known to turn out novels depending on his mood.

3.1 Professional Offerings

As stated earlier, there are a variety of choices in the word processor market. The ones I tried and examined were chosen both by their reputation and based on how easily I could get my hands on a copy.

3.1.1 Microsoft Word 2010

Microsoft Word 2010 is a powerful and expansive program. It has far more features and options than any of the other products I tested.

While Word has a selection of main controls at the top of the page that are relatively easy to interpret,

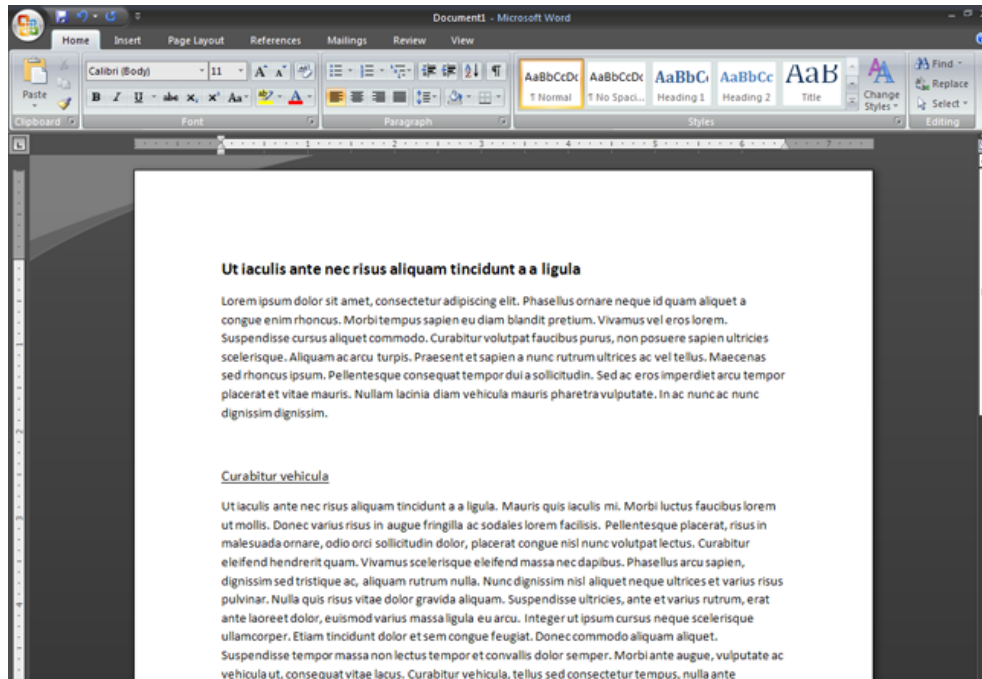

Figure 2: Microsoft Word 2010 with text.

most of the options and features are hidden under a variety of menus. Disabling features that many of my surveyees complained about, such as auto-correct, took a few minutes. This was because it was hard to find the right check box or drop down in Word's maze of menus.

Despite its weight, Word is incredibly powerful, and no matter what a user needs to do, Word should be able to do it.

3.1.2 Microsoft Word 5.5

Originally released in 1991[9], Microsoft Word 5.5 is an interesting beast. 5.5's initial downside is that it needs to be run in DosBox. The cool thing about DosBox though, is that it means I can run 5.5 on Linux and on just about every other machine that it supports. But 5.5 comes from before the days where everything is just one executable. The user install experience is incredibly slow and time consuming. 5.5 extracts approximately four hundred files before setup, and then another two hundred during the install process.

Once you are inside 5.5, the experience is relatively nice. Document navigation was done entirely via the keyboard. It reminded me a lot of Nano[1], and was a joy to use. The user can also select text with the mouse, and we can see how the experience in 5.5 turned into that of Microsoft Word 2010.

5.5 offered no color or font customizations, although the user could go full screen, which was very nice.

Figure 3: Microsoft Word 5.5.

Page breaks were implied with an emphasized dotted line.

3.1.3 Pages

The Apple offering in the word processor space. I found Pages rather nice to use, and its full screen mode was very similar to what I was looking to make. The downsides were simple though. Pages' default file type cannot be read by any other program or operating system, and you could do very little to customize the user interface.

3.1.4 OpenOffice

OpenOffice Writer 3 seems to be on-par with current Microsoft Word offerings. The product has a ton of features, most of which were hidden behind obscure icons and menus though.

Writer was nice in that it always opened a new empty document so you can start writing immediately.

The full screen mode also looked pleasant, but tended to crash when transitioning in and out.

Writer also had an easy to use “export to PDF” feature. Spell check was easy to find compared to many of the other programs examined.

You could customize a lot of things in Writer, but it was annoying that you had to select all of the text to change the document color scheme. In contrast though, Writer supported more fonts than any of the other

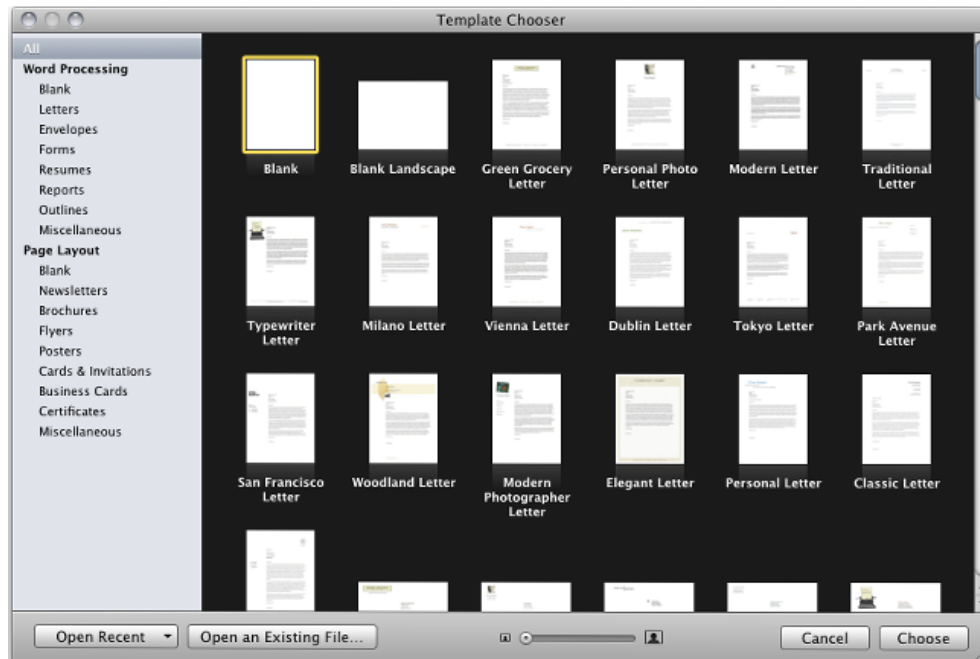

Figure 4: Pages' document forming selection window.

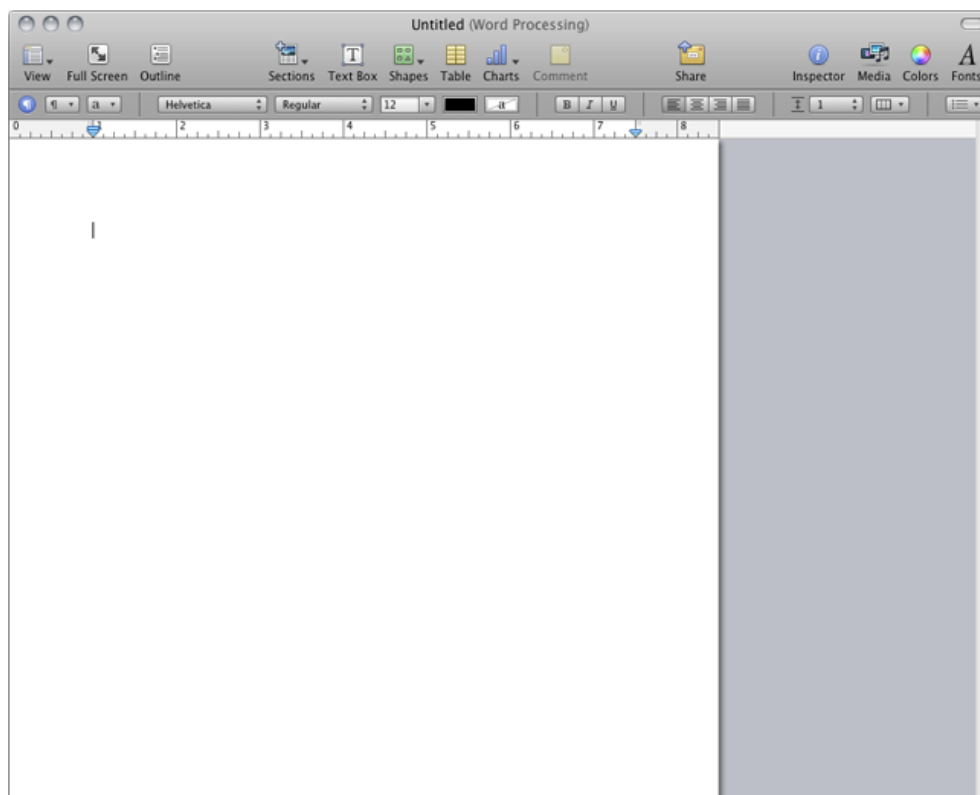

Figure 5: Pages with no text.

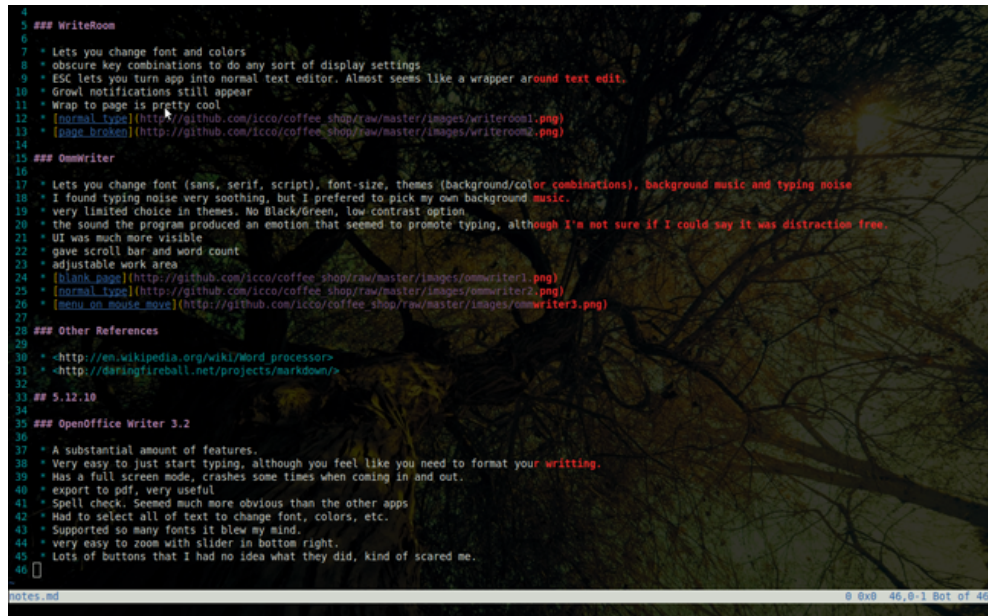

Figure 9: Vim with one file open.

3.2 Similar implementations

These are programs I am trying to emulate while developing coffee_shop.

3.2.1 WriteRoom

WriteRoom is a piece of software for OS X by HogBay Software [8]. By default WriteRoom opens in full screen. Pressing escape though turns the application into a normal windowed text editor. This windowed text editor looks very similar to OS X's Text Edit.

WriteRoom has a lot of cool customizations. It lets the user choose colors and fonts. It also does a really nice job wrapping and splitting up pages.

The only thing I found annoying was that you needed to know obscure key combinations to do change any sort of display settings. This seemed weird, because while key bindings let you keep the interface simple, users can't use them if they aren't taught them when the application opens.

3.2.2 OmmWriter

OmmWriter [5] is similar to WriteRoom in its feature set, except that it focuses around themes. Users select from a limited set of fonts, background and color combinations, background music, and typing noises.

The typing noise was quite an interesting idea. I tended to mute the background music, but noise of

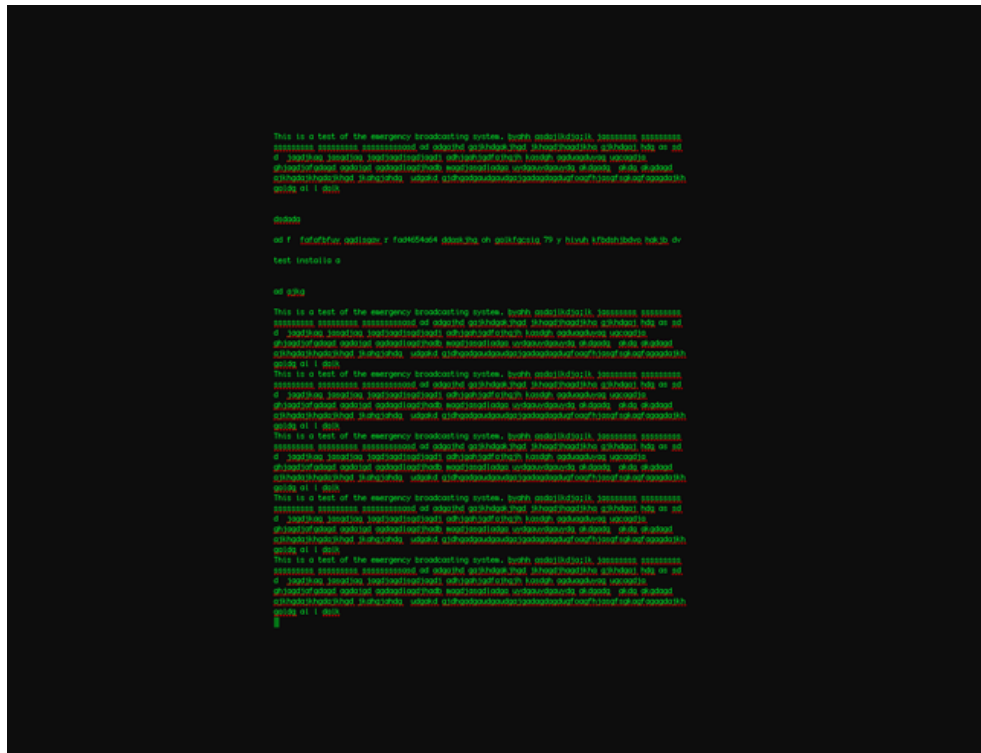

Figure 10: WriteRoom with one page of text.

clicking typewriter keys ended up being quite soothing.

Probably the biggest complaint comes from the limited number of themes. I was looking for a high contrast option, such as light green on a black field. There was nothing similar to this, and most themes were very low contrast and hard to read.

The workspace was adjustable in size, and the user interface came and went based on mouse movement and typing speed, which was a nice touch. OmmWriter seemed the most polished of everything I tried out, and was the program I tried the hardest to emulate.

4 coffee_shop

I've included a variety of screen shots of the complete project, see figures 15 through 21.

Figure 13: OmmWriter while typing.

Figure 21: coffee_shop's open dialog.

5 Evaluation of coffee_shop

Below is a list of requirements determined at the beginning of the project and whether or not coffee_shop passes them. In the following requirements, “it” refers to the application, coffee_shop.

5.1 Functional Requirements

FR1 It must allow the user to type into the application.

Passed.

FR1.1 As the user types, text will appear onto the screen.

Passed.

FR1.2 Certain keyboard shortcuts will cause the system to act in a predictable way. Such as CTRL+s will force the program to save the current working document.

Passed, although as find and replace is not supported, CTRL+f does not work.

FR2 It must be able to save and open the users work.

Passed.

FR3 The work environment must be customisable.

Passed.

FR3.1 The user should be able to select a background color.

Passed.

FR3.2 The user should be able to select a font color.

Passed.

FR3.3 The user should be able to select a font, from a limited selection of fonts.

Passed.

FR3.4 These setting should be saved between sessions.

Passed.

FR4 It must support find and replace.

Failed. I ran out of time and never implemented this.

FR5 It must be able to display a word count.

Passed.

FR6 When the user clicks the print menu item, the dialog to print must be displayed.

Passed. It prints as well.

5.2 Non-Functional Requirements

NFR1 It must be Open Source.

Passed. The application is available for download at https://github.com/icco/coffee_shop under the MIT License.

NFR2 The language it is written in must be Open Source.

Passed. The program is written in Ruby, which is available under the GPL v2 at <http://www.ruby-lang.org/en/>.

NFR3 It must run on Linux.

Passed.

NFR4 It must run full-screen.

Passed.

NFR5 It should promote a distraction free work environment.

Passed.

NFR6 It should be usable by people who work in various lighting environments (writing in a coffee shop, dark room, corporate environment).

Passed. I was able to use it in all three of these places.

NFR7 The format the work is saved in must be standards compliant format.

Passed. Saves in plain text.

5.3 Development decisions

I made some decisions while developing and designing `coffee_shop`, which may be considered controversial or unintelligent. The two big decisions I made were to use Ruby as my programming language and Qt as my graphics framework.

5.3.1 Ruby

Ruby is an interesting beast. I selected it because I had little experience with the language and it had a very large community online. Since starting the project I have learned a lot about the language.

Ruby is a really fun language to write in, but it is not made to develop systems whose state changes during its run, due to the fact that most methods return new objects instead of modifying the one passed in. Ruby works far better as a shell script or responder for a website because it can execute in entirety and doesn't need to jump around to a ton of objects already allocated. It's possible that a graphics framework could solve this, but I was unable to find one that did.

5.3.2 Qt

Qt is incredibly powerful, and `RubyQt` [6] is probably the best UI toolkit available for Ruby. But Qt is written for Java and C++. Qt expects to have references to everything, and wants everything to be passed by reference. Ruby doesn't really work this way and because of it, hindered Qt's power.

Interestingly enough, a lot of the things I saw other applications doing that I thought were cool, were actually areas where people were hacking directly on the Qt source, or rewriting entire sections of the library [4].

In hindsight, if I were to use Qt, I would use it with C++, instead of one of its many ports to other languages.

5.4 Features and their implementations

These are a variety of features that I either spent a lot of time on or thought a lot about.

5.4.1 File writing

File writing is a simple concept, but can be easily complicated. The question, as a developer, that you have to ask yourself, is if you want others to be able to open your files. Microsoft, Apple and OpenOffice all say no. Microsoft and OpenOffice provide specifications on how to read and edit some of their file types, but even that is kind of tricky.

So if you don't care about others, you can just dump all of the binary data you want, and just walk away. If you do care about others, you have a few more choices. First off, are you storing any other data besides plain text in your document? For me the answer was no, so I just decided to write to the file and give it a ".txt" extension by default. You could instead want to store meta-data along with your plain text, such as formatting information or user information. Suggestions for doing this would be to either use XML or another common markup language, and then output that in plain text. This way your files are still readable by all, but your program is the most optimal way to edit the data. The downside to this is that you need to verify the documents structure on file load so that you don't have malicious users injecting data into your application. Some might also complain that the file format will not be compressed. But then again, plain text is much easier for users to store and compress themselves.

One thing I thought heavily about once I had my file type set up, was how often to save. I decided saving automatically every minute was a great decision. Every single one of the people I surveyed wanted the functionality, and it was easy to implement.

5.4.2 Pagination

So, this is the one feature I really wanted to get work, but I just could not figure it out. It seems to be that Qt only wants to do pagination when the data is read only. So, for example, you can send Qt a block of text to print preview, and it will return you a read only set of paginated data. All of the actual text document objects do not support pagination while typing though, which makes them all pretty useless. Posting on the

Qt forums and on StackOverflow, the general opinion was that I should fork the Qt source and modify the “TextDocument” object myself in C++.

This made me furious, in what world is it good API design to make your library need to be modified to get a desired effect? I thought the internet was crazy, but I looked at the source of some of the major Qt users, such as KWrite, and was blown away. They reimplemented about half of the Qt framework because the framework didn’t do what they wanted to. On top of that, this reimplementation was close to two thirds of their code base. For such a large project it seems to me that it would be better if they submitted patches back to Qt instead, but oh well.

Frustrated, I tried to do pagination myself. I tried a variety of methods to split the data between text boxes. The problem with this was that whenever I did this, focus was put back on the top of first text box. So depending on how often I recalculated the pagination data, users would get incredibly incoherent data. The worst was when I recalculated pages after every key press. This made it so when users typed data went into the document backwards (as if they were pushing their characters onto a stack), but when they pasted, the text went in the right way.

After a while, I just moved on and abandoned the feature. I’ve written the Qt maintainers, and their response is not to use language wrappers, such as RubyQt, which was probably the most unhelpful response I have ever seen.

5.4.3 Printing

This was surprisingly easy thanks to Qt. All I really had to do was open a “Qt::PrintDialog”, which prompted the user to select a printer, and then send a block of text to the object representation of the printer they selected.

5.4.4 Customization and preference storing

Storing customizations was a pretty easy technical challenge. It required creating a singleton class, which let me store key value pairs to it. Then we would write out the changes to disk on occasion. We would also make sure all of the data got written out when the program exited.

The biggest problem was trying to support configuration changes while the program was running. Often Qt objects didn’t want to be redrawn. Unlike an element in the DOM tree which can be styled dynamically with ease, Qt often made strange choices when to redraw with the new settings it was given. It seems like these redrawing actions are a common problem in the Qt world. When I asked around Nokia and Qt’s

forums, I was told I should just modify the core Qt code to get the desirable effect I was looking for.

6 Future Work

I think there is lots of work to be done here, but I would argue against actually doing any it. Instead of continuing to develop this application, I would recommend looking into building a web application that simulates the same experience. CSS makes it easier to iterate quickly on the design and layout, plus you can use the HTML5 local storage API to let the user work offline.

If you were to continue working on this project, I would focus on making the application easier to deploy across a wide variety of operating systems. I would also try and find a layout that works well on all screen sizes.

7 Conclusion

I originally chose to jump into this project due to the fact that after five years I had never made a desktop application. So I decided that I would do this as a way to make sure I wasn't missing out on a part of the Computer Science field that I might be interested. I quickly discovered that I did not enjoy some of the major ideas behind desktop programming. I learned a lot, and I am proud of what I made, but I would not do this again. Instead I would develop the application for the web because I am more familiar with the technologies and enjoy developing for a system where the entire state refreshes on page reload.

I should say that despite how frustrating I found developing this application, the final product does work well. It is ugly and has a few bugs, but if you just want to edit text in Linux, it does the job.
